

Long profile

Describes the gradient of a river from source (steep) to mouth (gentle).

upper course: steep gradient, low discharge, high potential energy.

, míddle course: gradíent decreases, íncreasing discharge, lateral erosion.

-lower course: very gentle gradient, high discharge, deposition dominant.

Cross profile The river's cross-section at a particular point. The channel cross-profile includes only the river itself. The valley cross profile includes the river channel, valley floor, and the valley sides.

upper

steep sides,

shallow channel

Narrow, V shaped valley

middle wider valley floor, channel becomes wider

Lower very wide, flat valley floor, meanders, floodplains.

10683583

Erosion wearing away of land by a ríver. Abrasion: sediment scrapes against bed and banks. Attrition: sediment particles

knock into each other, becoming smaller/rounded. Hydraulic action: water enters cracks, air compressed, rock breaks apart. **Solution:** soluble minerals díssolve in river water.

Transportation The process by which a river carries its load. Traction: large boulders rolled

UK River Landscapes

along the riverbed. **Saltation:** smaller pebbles "bounced" along.

Suspension: fine sediment carried in the water column.

Solution: dissolved materials carried invisibly in water.

Deposition The process by which a

river drops its load. Occurs when a river loses energy (e.g., shallower water, decrease in velocity, or during low flow), e.g. during flooding, at the base of a waterfall, the inside of a meander, and at the mouth where it meets another body of water.

3. Land Forms

waterfalls and gorges

1. Occur where hard rock overlies softer rock 2. Undercutting of softer rock by hydraulic action and abrasion.

3. Undercutting leads to collapse of cap of more resistant rock.

4. Waterfall retreats upstream leaving a gorge.

Interlocking spurs

Projecting ridges of high land that alternate from each valley side where the river winds around more resistant rock in the upper course.

Bepositional l and for the s

and deeper, gently

sloping sides

Levées: Naturally raised riverbanks formed by coarse sediment deposited close to the channel edge during floods.

Silt deposits on the floodplain from previous flooding.

Ríver floods – largest material ís deposited at the edge of the channel thin and fine material transported further as less energy is need to

Natural levées increase in height as sediment is deposited following each flood event

Estuary: A wide, sheltered body of water found at a river's mouth, where it broadens into the sea.

transport it.

W internet geography

alternating pools and riffles creating variations in velocity that begin to direct the river's flow side to side, initiating a bend.

The river flows through

The bend becomes more pronounced because ongoing outer bend erosion and inner bend deposition create a deeper cun/e

Continued erosion (hydraulic action and abrasion) on the outer banks narrows the meander's neck, bringing opposite bends closer together.

channel

river may cut through the narrow leaving an oxbow lake isolated neck, forming a new, straighter from the main river.

Flood plain: Flood plains are associated with rivers in their middle and lower course. They are extensive, flat areas of land covered mainly by grass. Flood plains are formed during flood conditions.

meander migration. The outside bends erode laterally into the edge of the valley. Their position slowly moves downstream.

Ríver bluff - area of higher land along the edge of the flood plain

Meander scar

Meanders at Yarm

Tees Estuary

10,50*7*5 Engineering

Floodplain zoning: Controls what can be built on floodplains to reduce damage.

- Low cost, reduces future damage.
- Restricts land use, may not be an XX. option in existing urban areas.

Planting trees (afforestation): Increases ínterceptíon, reduces surface runoff.

Improves environment, reduces flood risk.

Takes time for trees to mature.

River restoration: Allows river to return to natural state (re-meandering, removing hard defences)

www creates habitats, aesthetically pleasing, can slow flow.

Can conflict with existing land use, initial costs.

W internet geography

UK River Landscapes

An increase in discharge causes river levels to increase. Flooding occurs when the bank full capacity of a river is exceeded (water spills over the banks of the river). Human and physical factors cause flooding.

Physical Factors

Heavy rainfall, prolonged rainfall (saturated ground), snowmelt, geology (impermeable rock), relief (steep slopes increase run-off).

Human Factors

urbanisation (impermeable surfaces), deforestation (less ínterceptíon), agrículture (reduced vegetation cover).

Ekojikeefiko

Hard engineering Involves the building of entirely artificial structures using various materials such as rock, concrete and steel to reduce, disrupt or stop the impact of river processes.

	Strategies	Advantages	Dísadvantages
	Dams and reservoirs	Store water, can generate hydroelectric power, controls flow.	Expensive, dísplaces people, can affect ecosystems downstream.
	Channel straightening	Speeds flow away from flood-prone areas.	Can íncrease floodíng downstream, expensíve, unnatural.
	Embankments	Increases channel capacity.	Rísk of severe flooding if they fail.
	Flood-relief channels	Diverts water away from high-value areas.	Expensive, requires significant maintenance.

11. Flood Managernent

Jubilee River Flood Relief Channel ORiver Thames @ Funded by the EA - £330 million The Jubilee River is a flood relief channel. It was constructed to reduce the risk of flooding high-value areas such as Windsor and Eton by diverting water from the River Thames.

Management strategy:

Designed to reduce flood risk for

vulnerable communities.

- Issues: • An 11.7 km artificial channel Social: Protects thousands of homes but raises fairness • diverts excess water from the concerns for downstream areas.
 - Economic: High construction and maintenance costs
 - (~£110 million), though can reduce insurance premiums.
 - Environmental: Blends natural features but alters river habítats downstream.

Hydrograp)

Hydrograph A graph which shows the discharge of a river, related to rainfall, over a period of time.

Flashy hydrographs have a steep rising limb and a small lag time. This indicates that river discharge increases rapidly over a short period, indicating rainwater reaches the river very quickly. This means the river is more likely to flood.

A gentle hydrograph shows the river is at low risk of flooding. These types of hydrographs have a gentle rising limb and a long lag time, which means it takes longer for the peak rainfall to reach the river channel, so the river discharge is increasing slowly.

Factors affecting the shape of a hydrograph:

- · Basin shape
- · Slope
- · Landuse
- Soil type
- vegetation.

Thames.
